- Conclusions / Future Work

Introduction to IMPI

- Many high quality implementations of MPI are available
 - Both freeware and commercial
 - Freeware implementations tend to concentrate on portability and heterogeneity
 - Commercial implementations focus on tuning latency and bandwidth
- Allows for a high degree of portability between parallel systems

The Problem

- Each implementation of MPI is unique
 - Underlying assumptions and abstractions are different
 - Messaging protocols are custom-written for hardware
- Different MPI implementations cannot interoperate
 - Cannot run a parallel job on multiple machines while utilizing each vendor's highly-tuned MPI

A Solution

- The IMPI Steering Committee was formed to address these issues
- The Committee consisted of vendors who already had high-performance MPI implementations
- Main idea: propose a small set of protocols for starting a multi-implementation MPI job, passing user messages between the implementations, and shutting the job down
- Proposed standard: <http://impi.nist.gov/IMPI/>

LAM's Role in IMPI

- The LAM/MPI Team was asked to join as a non-voting member
- Continues a history of providing a freeware “proof of concept” implementation of proposed standards
- LAM/MPI Team provided both a first implementation of the IMPI protocol, but also an MPI-independent implementation of the IMPI server (described shortly)

Related Work

- PVMPI / MPI Connect: University of Tennessee
 - Use PVM as a bridge between multiple MPI implementations
- Unify: Eng. Research Center / Mississippi State University
 - Allows both PVM and MPI in a single program
- Problems with previous approaches
 - Use of non-MPI functions
 - Subset of MPI-1 (e.g., no **INTERCOMM_MERGE**)
 - Incomplete **MPI_COMM_WORLD**

- Conclusions / Future Work

IMPI Goals

- User goals
 - Same MPI-1 interface and functionality; any MPI-1 program should function correctly under IMPI.
 - Provide a “complete” **MPI_COMM_WORLD**
- Implementation goals
 - Standard way to start and finish multiple MPI jobs
 - Common data passing protocols between implementations
 - Distributed algorithms for collectives

Complete MPI_COMM_WORLD

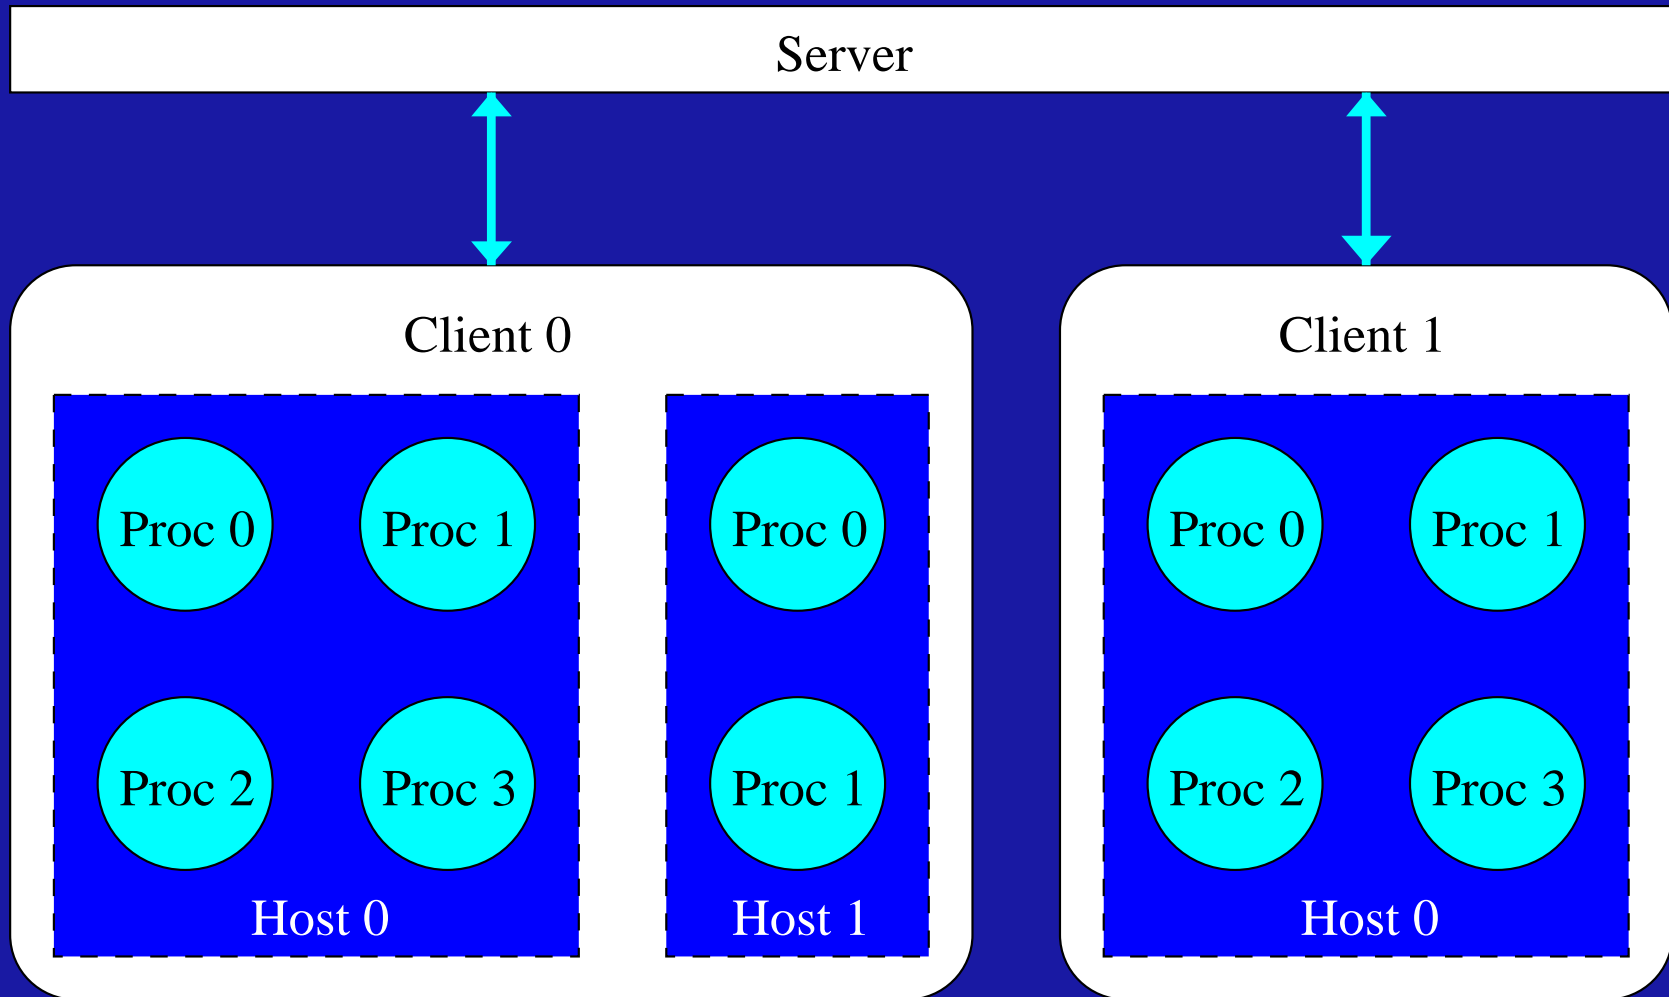

MPI_COMM_WORLD

Terminology

- Four main IMPI entities
 - **Server**: Rendezvous point for starting jobs
 - **Client**: One client per MPI implementation; connects to server to exchange startup/shutdown data
 - **Host**: Subset of MPI ranks within an implementation
 - **Proc**: Individual rank in **MPI_COMM_WORLD**

The Big Picture

Startup Protocol

- A two step process used to launch IMPI jobs:
 1. Launch the server
 2. Launch the individual MPI jobs
- The clients connect to the server and send startup information
- Server collates all information and re-broadcasts to all clients
- Clients use this data to form a complete **MPI_COMM_WORLD**

Connecting Hosts

- After the clients have received the server data, hosts make a fully-connected mesh of TCP/IP sockets
- User data will travel across these sockets (e.g., **MPI_SEND**)

Data Transfer Protocol

- Only messages *between* implementations are regulated in IMPI
- Messages within a single implementation are not standardized
- User data is passed between procs on different implementations via hosts
 - This causes a potential communication bottleneck
 - But IMPI communication is expected to be slow anyway
 - Note that a single implementation may have multiple hosts; those messages are not regulated

Message Packetization

- Messages between hosts are packetized
- Several values are negotiated during startup
 - **maxdatalen**: Maximum length of payload in IMPI packets
 - **ackmark**: Between each host pair, an ACK must be sent for every **ackmark** received packets
 - **hiwater**: Messages can continue to be sent until **hiwater** packets have not been acknowledged

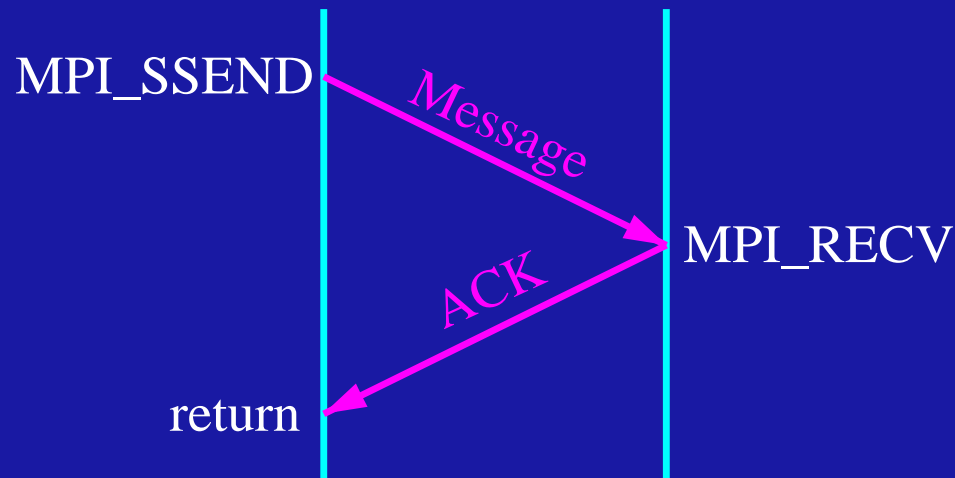

Data Protocols

- Short message protocol
 - Non-synchronous messages \leq **maxdatalen** bytes are sent eagerly in one packet
- Long message protocol
 - Messages $>$ **maxdatalen** bytes are fragmented into packets of **maxdatalen** bytes
 - The first packet is sent eagerly (like short messages)
 - The receiver will send an ACK when it has allocated resources to receive the rest of the message

Synchronous Messages

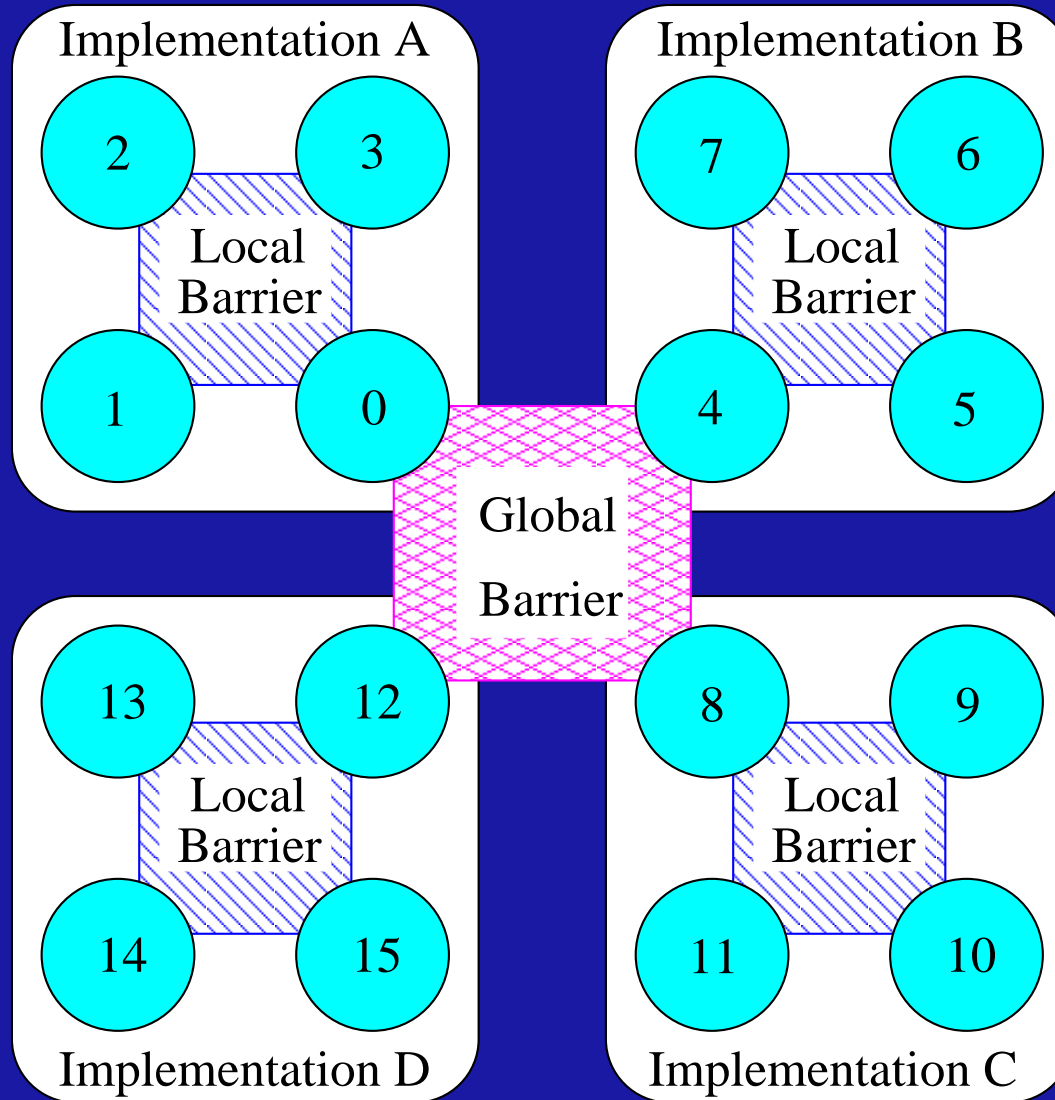

- **MPI_SSEND**: Returns when message has begun to be received
 - Always uses the long message protocol
 - Can use the ACK in the long protocol

Collective Algorithms

- IMPI implementations must share common collective algorithms so that they know their role in the larger computation
- Affects both data-passing collectives (e.g., **MPI_BCAST**) and communicator constructor / destructors (e.g., **MPI_COMM_SPLIT**)
- Pseudocode for all MPI collectives are in the IMPI standard
 - Utilizes very low cross-implementation communication
 - Usually has “local” and “global” phases

MPI_BARRIER Collective Algorithm

NIST Conformance Tester

- NIST has implemented a Java applet to test IMPI implementations
 - Emulates IMPI server, clients, hosts, and procs
 - C source code provided to compile / link against the IMPI implementation being tested
 - Run the resulting program, link up to the Java applet
 - A series of tests can be run from the Java client
- Available on the NIST IMPI web site

Shutdown Protocol

- As each proc enters **MPI_FINALIZE**, it sends a message to its host indicating that it is finished
- When a host gets finalize messages from all of its procs, it sends a message to its client
- Similarly, the client sends a message to the server when its hosts are finished
- The server quits when it receives a message from each client

- Conclusions / Future Work

LAM/MPI Overview

- Multiple original LAM developers were on the IMPI Steering Committee; the design of IMPI is similar to that of LAM/MPI
- Originally written at OSC as part of the Trollius project, now developed and maintained at Notre Dame
 - Full MPI-1.2 implementation, much of MPI-2
 - Multi-protocol shared memory / network protocols
 - Persistent daemon-based run-time environment, used for process control and out-of-band messaging of meta data

Code Structure

- Divided into three main parts: MPI layer, Request Progression Interface (RPI), and the Trollius core

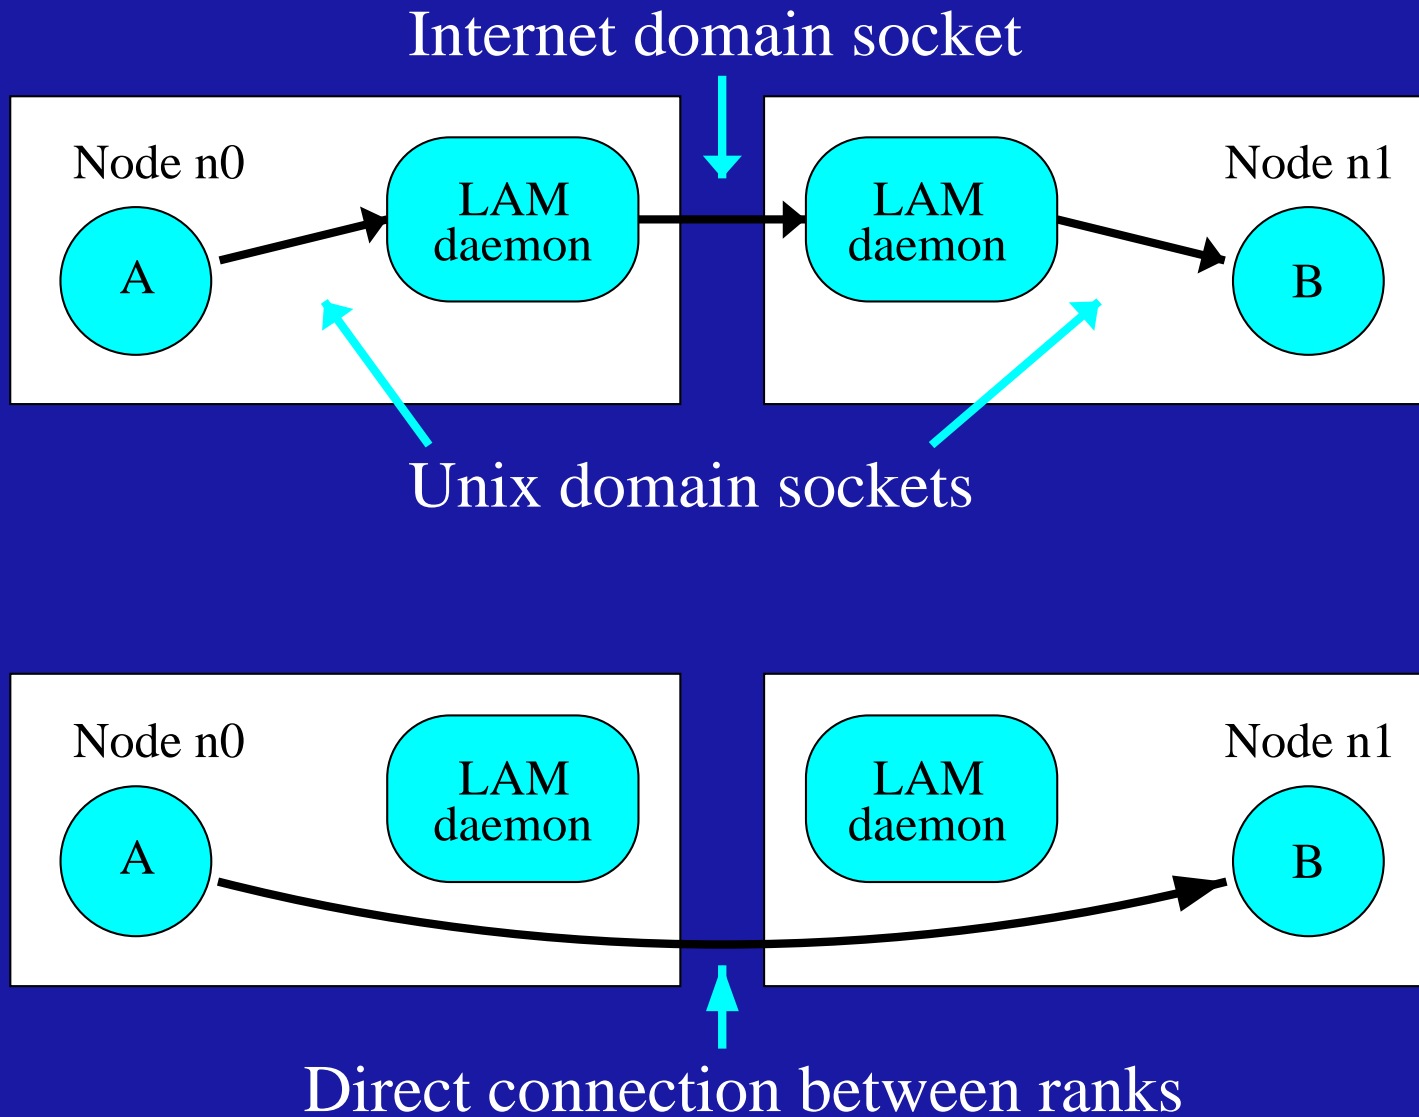

Code Structure

- MPI Layer
 - Every communication is a *request* (i.e., **MPI_Request**)
 - Creates and maintains communication queues of requests
 - e.g, **MPI_SEND** generates a request and places it on the appropriate queue
- Trollius Core
 - Provides a backbone for most services, including the LAM daemons
 - Contains most of the “kitchen sink” functions for LAM/MPI

Request Progression Interface (RPI)

- Responsible for all aspects of communication; the RPI progresses the queues created in the MPI layer
- Rigidly defined layer – has a published API
- Two classifications of RPIs: **lamd** and **c2c**
 - **lamd**: Daemons based – slower, but more monitoring and debugging capabilities available
 - **c2c**: Client-to-client – faster, no extra hops

lamd and c2c RPI Diagrams

c2c RPIs

- LAM currently includes three **c2c** RPIs:
 1. **tcp**: Uses internet domain sockets between all ranks
 2. **sysv**: Same as **tcp**, but uses shared memory to communicate between ranks on the same node; SYSV semaphores used to lock memory
 3. **usysv**: Same as **sysv**, but spin locks used to lock memory

Overall Goals

1. The IMPI client and host will be implemented in a separate daemon, (the **impid**)
2. There will only be one **impid** per IMPI job; only one IMPI host will be supported
3. The **impid** must be transparent to the user; it will automatically be started, die gracefully when the program finishes, and be able to be killed by the **lamclean** command on error
4. The **impid** must be able to use any of the four existing RPIs

How the impid Fits In

Connections to other IMPI hosts

IMPI Job Startup

- Start the IMPI server somewhere
- **mpirun -np 4 -client <server-ip> <server-rank> a.out**
- **impid** is an “almost MPI” process
 - Is started via **MPI_COMM_SPAWN** during a.out’s **MPI_INIT**
 - Invokes **MPI_INIT** / **MPI_FINALIZE** itself
 - Uses MPI calls for the majority of message passing between local LAM ranks
 - Receives **<server-ip>** and **<server-rank>** from **mpirun**

The impid

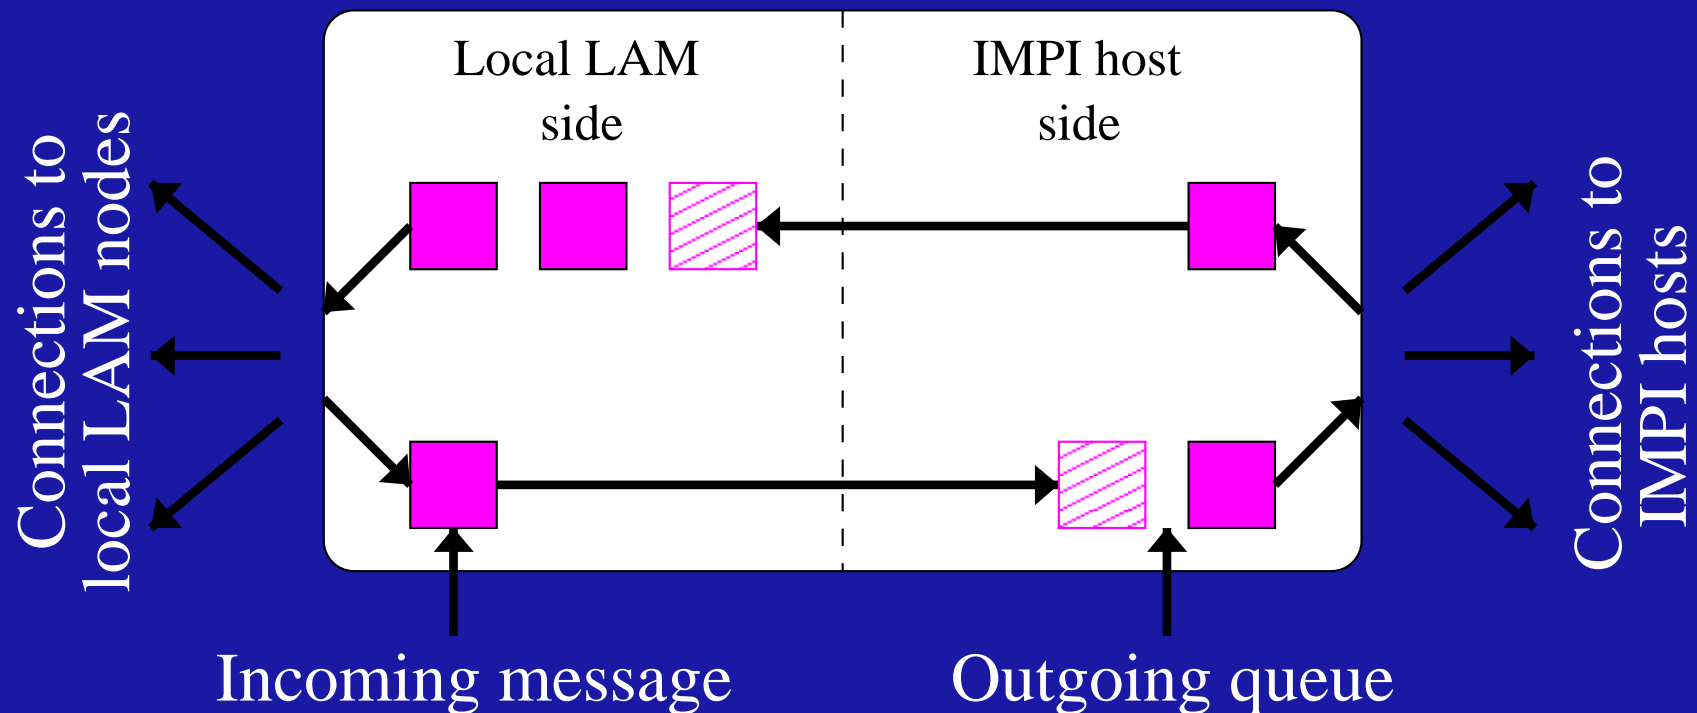

- Provides some degree of asynchronous communication since it is a separate process
 - For example, **MPI_SEND** to a remote proc can return long before the message is actually received
 - Can allow for overlap of communication / computation
 - Especially important over high latency links
- Communicates with local LAM ranks using the current RPI
- Allows for multiple simultaneous IMPI jobs within a single LAM

impid Design

- **impid** is split in half: one side communicates with the local LAM ranks, the other side communicates with the other IMPI hosts
- Could not use threads; spinning necessary
 - Use blocking **poll(2)** system call to check for messages on host side, and **MPI_TESTANY** to check for completion on local LAM side
 - Cannot block while communicating; persistent / non-blocking modes used to communicate with local LAM ranks
- Host side must obey flow control rules

impid Design (continued)

- Messages that enter one side generally exit the other
- Queuing system used on host side because of long message protocol and flow control

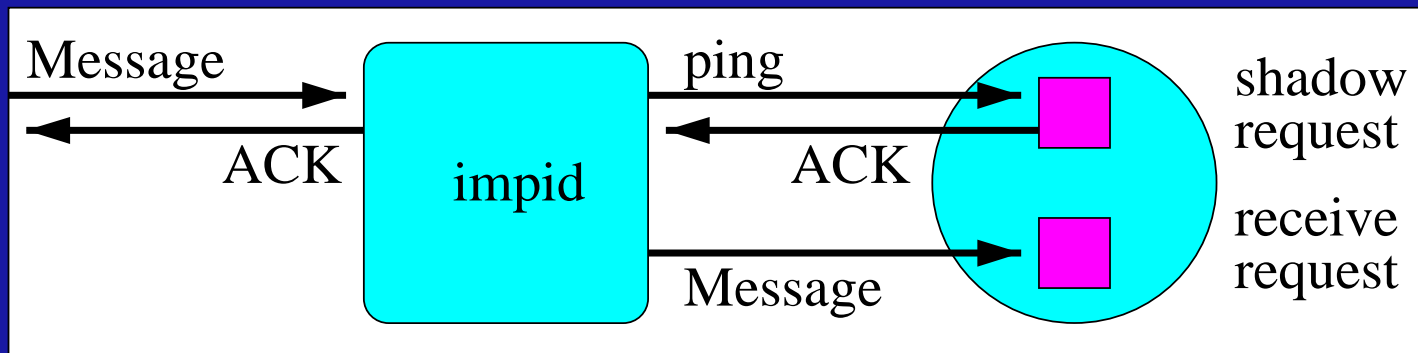

General Operation

- Sending messages
 - If a message is destined for a proc on a remote host, its request is re-routed in the MPI layer to the **impid**
 - The **impid** then sends the message to the remote host according to the long / short protocols
- Receiving messages
 - Similarly, if receiving from a remote proc, MPI layer redirects the request to receive from the **impid**
 - Complications arise for synchronous mode sends

Shadow Requests

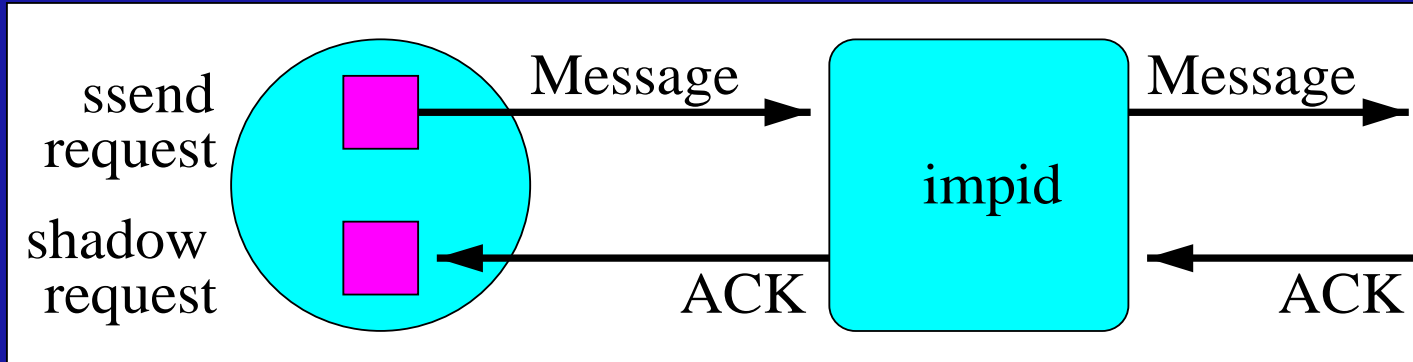

- No way for **MPI_RECV** to know if incoming message will be synchronous before message is received; must send ACK if so
 - Post *two* receives; second receive is a “shadow”

- If message was not synchronous, shadow receive is canceled after message is received

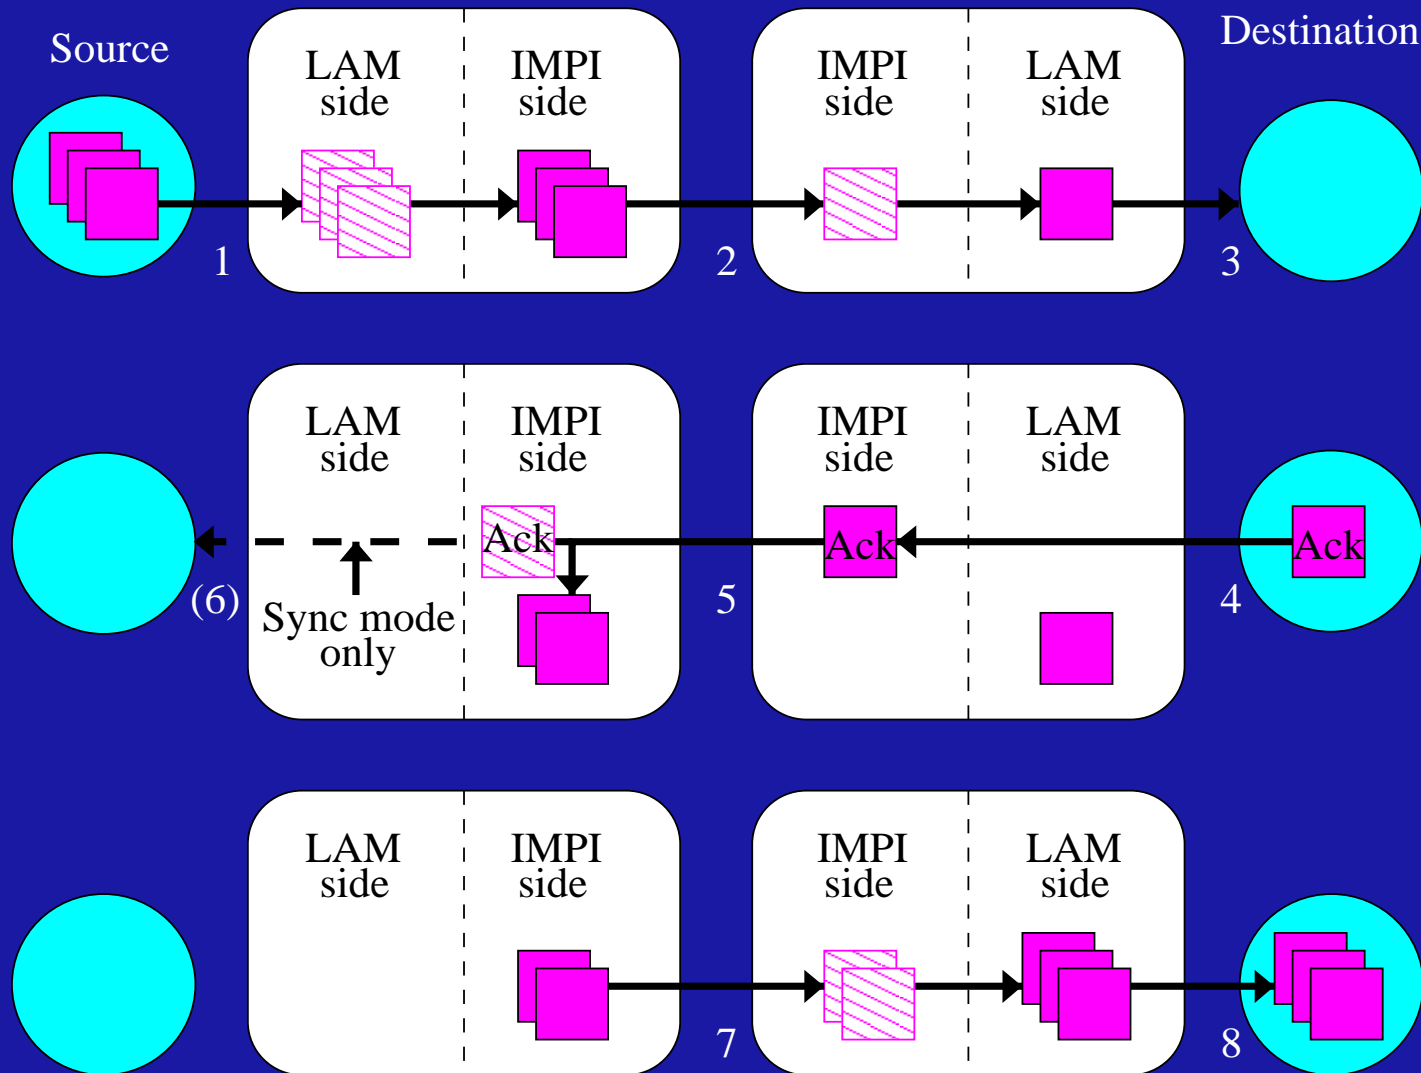

Synchronous Sends

- Similarly, synchronous sends must post a shadow receive

- Shadow requests are new for IMPI – added significant complexity in **MPI_WAIT** and **MPI_TEST**

Example: Sending a Long Message

Limitations of Implementation

- Except for **MPI_BARRIER**, no MPI collectives implemented
 - Data-passing collectives not hard to implement
 - Communicator constructor / destructor collectives will probably require a redesign
- **MPI_CANCEL** is not implemented for sends of messages

Overview

- Results
- Conclusions / Future Work

Experimental Setup

- Two unloaded 400Mhz Pentium-II machines, Linux 2.2.12
 - One located at Notre Dame (Indiana, USA)
 - Other located at Lawrence Berkeley Labs (California, USA)
- Each on local 100Mbps switched networks
- Aggregate bandwidth at time of test was 2.3Mbps
- Standard ping-pong test (messages of 100 bytes to 1Mbyte)
 - **Test one**: two LAMs connected via IMPI
 - **Test two**: one LAM spanning both machines

Round Trip Times (ms) vs. Message Size

Green: times for IMPI (2 LAMs)

Blue: times for one LAM

Is This Bad?

- It's not good, but it's not bad
- IMPI communication is *supposed* to be slow (by design)
- The value is that it works and is not horrendous
 - Can connect highly tuned MPI implementations
 - Well written MPI codes can utilize high-latency links properly, and overlap communication and computation
 - Need at least one vendor-tuned IMPI to see true benefits

Overview

- Introduction
- IMPI Overview
- LAM/MPI Overview
- IMPI Implementation in LAM/MPI
- Results
- Conclusions / Future Work

Conclusions

- IMPI works
- Now we need support for IMPI in other MPI implementations
- Future work for LAM:
 - Finish data-passing and constructor collectives
 - Optimize collectives over distributed links
 - Restructure LAM/MPI for generic multi-protocols
 - Thread support
